Your radiologist is a doctor who specializes in the diagnosis and treatment of diseases and injuries, using medical imaging techniques such as X-rays, computed tomography (CT), magnetic resonance imaging (MRI), nuclear medicine, positron emission tomography (PET), imaging synthesis and ultrasound. Since some of these imaging techniques involve the use of radiation, and requires training to understand radiation safety and protection. Your radiologist graduated from accredited medical school, passed the exam license, and completed residence of at least four years of unique postgraduate medicine education in, among other topics: Radiation safety /protection Radiation effects on the human body Appropriate implementation and interpretation of quality X-ray and medical imaging Examinations The majority of radiologists also completed a scholarship - one to two additional years of specialized training in a specific subspecialty of radiology, such as imaging of breast, cardiovascular radiology or nuclear medicine. Your radiologist plays a key role in your healthcare by acting as an expert consultant to your asking doctor (the doctor who sent you to the radiology department or research clinic) by assisting him/her in choosing an appropriate examination, interpreting the received medical images and using test results to target your care. Treatment of diseases by radiation (radiation oncology) or minimally invasive, image-based therapeutic intervention (interventional radiology). Related to medical imaging findings with other studies and tests. Recommend additional appropriate research or treatment when necessary and provide requesting physicians. Targeting radiological technologists (staff working with equipment) in the proper conduct of quality examinations. Your radiologist Has the right training, knowledge and experience When your doctors who tell you they have reviewed your research, what they usually mean is that they have reviewed the radiological report or passed the imaging exam with your radiologist. Radiologists are at the forefront of imaging technology, pioneers use CT, MRI, PET and fusion imaging, as well as minimally invasive procedures such as endovascular treatment of aneurysms and tumors, percutaneous biopsies and radiation therapy. Radiologists certified by the American Radiology Council (for physician) or the American Osteopathic Council on Radiology (for the osteopathic physician) show the highest level of training and demonstrate excellence in the field. Radiological procedures such as CT, MRI and PET are medically prescribed and should only be carried out by appropriately trained and certified doctors under medically necessary circumstances. Radiologists are doctors who have received at least four years uniquely, post-smokeological school training in radiation safety, optimal implementation of radiological procedures and interpretation of Images. Other medical specialties assign much less imaging, ranging from several days to a maximum of 10 months. The use of medical imaging procedures by unqualified providers may unnecessarily expose you to levels of radiation or radiation that could be unreasonably dangerous. This can lead to misdiagnosis or problems that are not diagnosed at all. Dictionary &g Examples of radiological is not in the Cambridge Dictionary yet. You can help! He may use X-ray machines or other such radiation devices. It also uses techniques that do not involve radiation, such as MRI and ultrasound. General types of radiology As a medical specialty, radiology can refer to two sub-fields, diagnostic radiology and therapeutic radiology. Diagnostic radiology refers to the use of various ways of imaging to help diagnose the disease. Diagnostic radiology can be further divided into multiple sub-special areas. radiology, one of these sub-special areas, uses the radiology imaging module to guide minimally invasive surgical procedures. Curative radiology or, as it is now called, now, oncology uses radiation to treat diseases such as cancer, using a form of treatment called radiation therapy. Imaging Commonly used imaging methods include simple radiography, computed tomography (CT), magnetic resonance imaging (MRI), ultrasound, and nuclear imaging technique. Each of these conditions has strengths and limitations that dictate its use in diagnosis. Radiographic X-rays are images created with X-rays, and are used to assess many bone and soft tissue structures. Fluoroscopy and angiography are special applications of X-ray image. Fluoroscopy is a technique in which a fluorescent screen or amplified tube image is connected to a closed television system with a closed image of the internal structures of the body. Angiography uses methods to prove the internal structure of blood vessels, emphasizing the presence and degree of blockage of the vessel, if any. In medical imaging, contrast media are substances that are administered in the body, usually injected or ingested to explain the anatomy of blood vessels, genitourinary tract, gastrointestinal tract, etc. The contrast medium, which strongly absorbs X-ray radiation, in connection with the ability to images in real time of fluoroscopy and angiography, help to demonstrate dynamic processes, such as the peristalsis of the digestive tract or blood flow. Ct imaging scans use X-rays in conjunction with computational algorithms for image tissues in the body. The image is usually carried out in the axial plane; However, computer reconstructions can be carried out in other planes or produce 3D images. Contrast environments are often used to outline anatomy and allow 3D reconstructions of structures, such as arteries and veins. Although the resolution of radiographs is higher for the imaging of the skeleton, CT can generate much more detailed images of soft tissues. CT exposes the patient to more ionizing radiation. Sonography Medical ultrasound (high-frequency sound waves) to visualize soft tissue structures in the body in real time. Radiation is not included, but the quality of the images obtained by ultrasound depends to a large extent on the skills of the person performing the exam. Ultrasonic procedures are best used for antatal examinations. It's not harmful to the fetus, nor to the mother. MRI Magnetic resonance imaging MRI uses strong magnetic fields to align the rotation of atomic nuclei (usually hydrogen proton) within the tissues of the body, then disrupts the axis of rotation of these nuclei and observes the radio frequency signal generated as the nuclei return to their source state. MRI scanning gives the best contrast to the soft tissues of all types of imaging. As the speed of and spatial resolution and improvements in computer 3D algorithms and hardware, MRI has the potential for major development over the next few years. One drawback is that the patient should keep for long periods of time in noisy, noisy, Nuclear medicine nuclear medicine is associated with the patient's application of substances labelled with radionuclides or radiopharmaceuticals that have an affinity for certain tissues. Generally speaking, Technetium-99m (half-life 6.02 hours) is the radionuclide used. The heart, lungs, thyroid, liver, gallbladder, and bones are often assessed for certain conditions using these techniques. While anatomical details are limited in these studies, nuclear medicine is useful for showing physiological function. Processes such as tumor growth can be observed in this way, even when the tumor can not be adequately visualized with the help of any of the other forms of imaging. Nuclear medicine also includes therapeutic use of isotopes labelled for antibodies or other substances, which is why a high dose of radiation is supplied for specific purposes such as tumors or thyroid. Normal Radiological Anatomy Imaging of specific anatomical regions This section suggests that you already know what the diagnosis is, and you just want to know more about this disease. Diagnosis of specific anatomical regions This section suggests that you do not yet know the diagnosis, and you are trying to move from the findings to the diagnosis.
